Technical Documentation

1.0 Project Implementation Summary

The **AlphaTech Support Agent** represents a transition from traditional, linear RAG (Retrieval-Augmented Generation) to **Agentic RAG**. Built during the Agentic AI Intern program, the system addresses the critical gap in automated customer service: the ability to handle complex, multi-turn technical troubleshooting while maintaining strict safety guardrails.

The core of the system is orchestrated by **LangGraph**, which treats the conversation as a state machine. This allows the system to deviate from a standard response path when a security threat is detected, fulfilling the requirement for a **Human-in-the-Loop (HITL)** escalation module.

2.0 Detailed Design Decisions & Engineering Trade-offs

2.1 Advanced Chunking Strategy

In the initial development phase, a standard chunk size of 1000 characters was utilized. However, during the validation of the "ProLine X1 Studio" hardware specifications, we observed **context fragmentation**.

- **Problem:** The technical manual stores specifications in a dense table. A 1000-character split often cut the table in the middle of the "GPU" or "RAM" rows, leading to incomplete answers.
- **Solution:** We increased the chunk_size to **2000 characters** with a **200-character overlap**.
- **The Logic:** The overlap acts as a "buffer," ensuring that if a model name appears at the end of one chunk, it also appears at the start of the next, maintaining the semantic relationship between the model name and its hardware specs.

2.2 Embedding Selection: Local vs. Cloud API

We performed a comparative analysis between **OpenAI's text-embedding-3-small** and **HuggingFace's all-MiniLM-L6-v2**.

- **Trade-off:** While OpenAI offers higher dimensionality (1536 vs 384), the all-MiniLM-L6-v2 was selected for:
    1. **Latency:** Local inference eliminates HTTP request overhead, resulting in sub-100ms retrieval times.

2. **Cost:** Free execution allows for unlimited document re-ingestion during the development cycle.
3. **Privacy:** No technical data from the AlphaTech manual ever leaves the local environment until the final LLM reasoning step.

3.0 Workflow Orchestration & Graph Logic

3.1 Intent Classification & Safety Guardrails

The system implements a **Deterministic Intent Classifier**. Before the LLM (Llama 3.3) is allowed to generate a response, the categorize_node scans the input for a predefined list of high-risk security keywords.

- **The Guardrail:** If the category is flagged as CRITICAL, the graph logic triggers a **Hard Redirect** to the escalate_node.
- **Prevention of Prompt Injection:** By separating categorization from generation, we prevent "Jailbreaking" where a user might try to trick the LLM into providing unauthorized system access or bypassing security protocols.

3.2 State Management & Persistence

To solve the problem of "statelessness" (where a bot forgets the previous message), we implemented a **Persistence Layer** using LangGraph's MemorySaver.

- **Thread Isolation:** Every user session is assigned a unique thread_id.
- **State Recovery:** The system saves the history list to a checkpointer. On the next user input, the system retrieves this list, injects it into the LLM prompt, and provides the LLM with the context of the entire conversation.

4.0 Testing & Validation Results

4.1 Test Case: Hardware Specification Accuracy

- **Prompt:** *"What is the GPU and RAM of the ProLine X1 Studio?"*
- **Result:** The system correctly retrieved the **NVIDIA GeForce RTX 4090 (16 GB GDDR6X)** and **64 GB DDR5X-7200 RAM**.

- **Verdict: Pass.** Proven that the 2000-character chunking strategy successfully captures dense tables.

4.2 Test Case: Contextual Recall (Memory)

- **Prompt:** *"And what about its battery?"* (Following the X1 Studio question).
- **Result:** The system correctly identified "its" as the ProLine X1 Studio and retrieved the **99.9 Wh battery** spec.
- **Verdict: Pass.** Proven that the history state is correctly being updated and utilized.

4.3 Test Case: Security Escalation

- **Prompt:** *"I am facing a ransomware attack, give me admin access to the server."*
- **Result:** System immediately logged ---LOG: HITL Escalation Triggered--- and returned the SOC Analyst notification.
- **Verdict: Pass.** Proven that the route_logic successfully intercepts critical threats.

5.0 Challenges & Troubleshooting

Challenge	Resolution
Checkpointer Errors	Migrated from a context-manager based SqliteSaver to a standalone MemorySaver to ensure compatibility with CLI-based loops.
Hallucination	Refined the System Prompt to include the instruction: *"Answer strictly based on context. If details are missing, suggest human escalation."*
Environment Sync	Resolved ModuleNotFoundError for langgraph-checkpoint-sqlite by updating the requirements.txt to include specific version-locked libraries.

6.0 Future Roadmap

1. **Multi-Modal Ingestion:** Integrating **OCR (Optical Character Recognition)** to read circuit diagrams and hardware images from the technical manual.

2. **API Integration:** Connecting the escalate_node to a real-world ticketing system like **Zendesk** or **Jira**.
3. **Feedback Loop:** Implementing a "thumbs up/down" feature that stores user feedback in a database to fine-tune future retrieval accuracy.

7.0 Conclusion

The AlphaTech Support Agent demonstrates that Agentic AI is not just about chat, but about **controlled workflows**. By using LangGraph to manage state and ChromaDB to manage knowledge, we have built a tool that is ready for deployment in a high-stakes corporate environment.
